A ZVI (Zones of Visual Influence) calculation is performed before flicker calculation so non visible WTG do not contribute to calculated flicker values. A WTG will be visible if it is visible from any part of the receiver window. The ZVI calculation is based on the following assumptions:

Height contours used: Height Contours: CONTOURLINE_Big Bend SFA.wpo (3)

Obstacles not used in calculation

Eye height for map: 1.5 m

Grid resolution: 1.0 m

All coordinates are in

UTM (north)-NAD83 (US+CA) Zone: 15

Table layout: For each day in each month the following matrix apply

Day in month	Sun rise (hh:mm)	First time (hh:mm) with flicker	(WTG causing flicker first time)
	Sun set (hh:mm)	Minutes with flicker	Last time (hh:mm) with flicker
			(WTG causing flicker last time)

Table layout: For each day in each month the following matrix apply

Day in month	Sun rise (hh:mm)	First time (hh:mm) with flicker	(WTG causing flicker first time)
	Sun set (hh:mm)	Last time (hh:mm) with flicker	(WTG causing flicker last time)

1.0 PROJECT OVERVIEW

Big Bend Wind, LLC (Big Bend or Applicant), an affiliate of Apex Clean Energy, LLC (Apex), is proposing to construct a wind energy generation facility, including up to 55 turbines and associated necessary project infrastructure, in Cottonwood County and Watonwan Counties, Minnesota (hereafter referred to as the Project) (see Figure 1). This report provides an assessment of the potential shadow flicker that could be experienced at residences located around the proposed turbines.

Several wind turbine generators are being considered for this Project. For this analysis, the turbine model evaluated is the General Electric G158 turbine. Each wind turbine consists of three major mechanical components: the tower, nacelle, and rotor. For the GE158, the anticipated tower height or “hub height” (height from foundation to the center of the rotor), for each turbine is approximately 107.4 meters (352 feet) and the rotor diameter is 158 meters (518 feet), resulting in a total maximum height of 186.4 meters (611.5 feet). The current Project turbine layout is depicted in Figure 2.

The Project is located within Cottonwood and Watonwan Counties, Minnesota, approximately 7 miles northeast of the City of Windom and 30 miles north of the Minnesota-Iowa border. Elevations in the area range from approximately 1,100 feet above mean sea level (amsl) to 1,460 feet amsl. Land cover within the Project area is dominated by active agriculture, with farms and single-family residences generally occurring along the road frontage.

2.0 INTRODUCTION

Shadow flicker refers to the moving shadows that an operating wind turbine casts at times of the day when the turbine rotor is between the sun and a receptor’s position. Shadow flicker is most pronounced in northern latitudes during winter months because of the lower angle of the sun in the winter sky. However, it is possible to encounter shadow flicker anywhere for brief periods after sunrise and before sunset (U.S. Department of the Interior, 2005). During intervals of sunshine, wind turbine generators will cast a shadow on surrounding areas as the rotor blades pass in front of the sun, and if these moving shadows pass over a window they can cause a flickering effect. Shadow flicker does not occur when fog or clouds obscure the sun, or when turbines are not operating.

The distance between a wind turbine and a potential shadow-flicker receptor affects the intensity of the shadows cast by the blades, and therefore the intensity of flickering. Shadows cast close to a turbine will be more intense, distinct, and focused. This is because a greater proportion of the sun’s disc is intermittently blocked by the turbine (BERR, 2009). Obstacles such as terrain, vegetation, and/or buildings occurring between receptors and wind turbines may significantly reduce or eliminate shadow-flicker effects. At distances beyond roughly 10 rotor diameters (approximately

1,580 meters based on the GE158 turbine model) shadow-flicker effects are generally considered negligible (BERR, 2009; DECC, 2011; DOER, 2011).

The location and duration of shadow flicker can be predicted using computer modeling programs and input data regarding turbine characteristics and weather conditions. A “worst-case” shadow-flicker scenario could be predicted based on the assumptions that there are no clouds or fog, wind conditions allow continuous turbine operation, the turbine rotor is continuously perpendicular to the sun, and the turbine rotor is positioned between the receptor and the sun. However, this “worst-case” scenario is not realistic because turbines do not operate continuously, are not always aligned perpendicular to the sun, and are not always positioned between the receptor and the sun. In addition, sunlight intensity and duration vary daily and seasonally, and obstacles that block shadows (terrain, vegetation, and buildings) exist in the landscape.

3.0 METHODS

3.1 Shadow Flicker Analysis

This shadow flicker analysis evaluated the potential impact of 55 GE158 turbines, each with a rotor diameter of 158 meters and a hub height of 107.4 meters. A maximum distance of potential effect of 1,580 meters (10 rotor diameters) was used for this analysis to ensure that all potentially impacted receptors were assessed.

The shadow flicker analysis for the proposed Project used *WindPRO 3.4* software and associated Shadow module. *WindPRO* is a widely accepted modeling software package developed specifically for the design and evaluation of wind power projects. Input variables and assumptions used for shadow flicker modeling calculations for the proposed Project include:

- The latitude and longitude coordinates of 55 proposed wind turbine sites (provided by the Applicant).
- The latitude and longitude coordinates of 969 potential residences located in the vicinity of the proposed turbines (provided by the Applicant).
- U.S. Geological Survey (USGS) 1:24,000 topographic mapping and USGS 10-meter resolution digital elevation model (DEM) data.
- The rotor diameter (158 meters) and hub height (107.4 meters) for the GE158 turbine model.
- Annual wind rose data (provided by Apex), which is depicted in Table A1 of Attachment A (to determine the approximate directional frequency of rotor orientation throughout the year).
- To account for the occurrence of cloudy conditions, the average monthly percent of available sunshine for the nearest National Oceanic and Atmospheric Administration (NOAA) weather station in Minneapolis – St. Paul,

Minnesota was used. Data were obtained from NOAA's "Comparative Climatic Data for the United States through 2015" (see Table A2 of Attachment A) (<http://www.ncdc.noaa.gov>).

- No allowance was made for wind being below or above generation speeds. Blades are assumed to be moving during all daylight hours when the sun's elevation is more than 3 degrees above the horizon. Shadow flicker is generally considered imperceptible when the sun is less than 3 degrees above the horizon (due to the scattering effect of the atmosphere on low angle sunlight) (States Committee for Pollution Control, 2002).

Shadow-flicker effects on receptors are expressed in terms of predicted frequency (hours per year). Shadow isolines (i.e., contours indicating total number of hours of shadowing per average year) were calculated based on the data and assumptions outlined above. These isolines define the theoretical number of hours per year that shadow flicker would occur at any given location within a 1,580-meter radius of all proposed turbine locations (see Figure 3).

The model calculations include the cumulative sum of shadow flicker hours for all Project turbines. This omni-directional approach reports total shadow flicker results at a receptor regardless of the presence or orientation of windows at that particular residence (i.e., it assumes shadows from all directions can be perceived at a residence, which may or may not be true). A receptor in this "greenhouse" model is defined as a one square meter area located one meter above ground; actual house dimensions are not taken into consideration.

Because the shadow flicker analysis conducted for the proposed Project was based on the conservative assumptions that 1) all 55 turbine locations modeled will be built, 2) the turbines are in continuous operation during daylight hours, and 3) that shadow flicker can be perceived at a receptor structure regardless of the presence or orientation of windows or the screening effects of all surrounding trees and buildings, the analysis presented herein is a conservative projection of the shadow-flicker effects at ground level.

3.2 Shadow Flicker Threshold

No consistent national, state, county, or local standards exist for allowable frequency or duration of shadow flicker from wind turbines. The Minnesota Public Utilities Commission has not promulgated any standards on shadow flicker. A threshold of 30 shadow flicker hours per year was applied to the analysis of the proposed Project to identify any potentially significant impacts on non-participating receptors.

4.0 RESULTS

Output from the model includes the following information:

- Calculated shadow-flicker time (days per year, maximum hours per day, and total hours per year when shadow flicker is expected) at each of the 969 receptors.
- Tabulated and plotted time of day that structures are predicted to receive shadow flicker.
- Shadow isolines, which are used to create maps showing turbine locations, receptors, and projected shadow-flicker duration (hours per year) without taking into consideration the effect of screening provided by vegetation and structures (see Figure 3).

These data are presented in the tables and calendars included in Attachment B.

A summary of the projected shadow flicker at each of the receptors is presented in Table 1 below.

Table 1. Summary of Projected Shadow Flicker

Hours/Year	Number of Receptors		
	Non-participants	Participants	Total
0	806	48	854
0 – 1	5	0	5
1 – 10	34	15	49
10 – 20	10	16	26
20 – 30	0	19	19
Over 30	0	16	16
Max Hours/Year	19:39	56:07	--

As these results indicate, 953 (98%) of the receptors are predicted to receive less than 30 hours of shadow flicker per year, with 908 (94%) of the receptors predicted to receive less than 10 hours of shadow flicker per year. At most receptor locations shadow flicker will occur primarily in the early morning or late afternoon. The maximum daily duration of shadow flicker predicted at any receptor is 1 hour and 54 minutes (at receptor 1, see Attachment B).

Attachment B provides the results of the predicted shadow flicker at each structure. The times of day and duration of shadow flicker experienced by each structure will vary throughout the calendar year based on the position of the sun in the sky and the direction of prevailing winds. See Attachment B for a table indicating the amount of shadow flicker expected at each receptor. For receptors over 30 hours, detailed calendars that illustrate the specific times of year and day that shadow flicker may occur are included within Attachment B. A table of results for all receptors is included as Attachment C.

5.0 DISCUSSION

As outlined above, results of the shadow flicker analysis for the Facility indicate that up to 16 receptors could experience more than 30 hours of shadow flicker per year. However, all of these receptors are located on properties owned by Project participants. The details regarding anticipated shadow flicker at all receptors predicted to receive in excess of 30 hours are summarized below in Table 2.

¹ Results do not account for the screening effect of trees, orientation of windows, hours of no turbine operation, or hours when turbines will be oriented to cast shadows away from the residences.

Although shadow flicker results presented in Table 1 theoretically exceed the 30-hour per year threshold, these calculations do not take into account the actual location and orientation of windows, or the screening effects associated with existing, site-specific conditions and obstacles such as trees (i.e., does not take into account the results of a viewshed analysis) and/or buildings. Further, this analysis assumes turbine rotors are continuously in motion and that each receptor location is occupied year-round.

Given these assumptions, the predicted shadow-flicker frequency represents a conservative scenario, and almost certainly overstates the actual frequency of shadow flicker that would be experienced at any given receptor location.

In addition, many of the modeled shadow flicker hours are expected to be low intensity because they would occur during the early morning or late afternoon hours when the sun is low in the sky. As the sun sinks below the horizon, more of its light is scattered by the atmosphere, which has the effect of dampening its brightness and therefore reducing its ability to cast dark shadows (EMD, 2013).

6.0 CONCLUSIONS

WindPRO predicted that 16 receptors will receive more than 30 hours/year of shadow flicker from the Project wind turbines. However, all of the receptors are located on properties owned by Project participants. More generally, the assumptions underlying the shadow flicker analysis are conservative. The analysis does not take into account important real-world factors, including the actual location and orientation of windows and the screening effects associated with existing, site-specific conditions and obstacles such as trees and/or buildings. Also, the analysis assumes turbine rotors are in continuous motion. Given these assumptions, the predicted shadow-flicker frequency represents a conservative scenario and likely overstates the actual frequency of shadow flicker that would be experienced at any given receptor location.

Shadow-flicker areas and isolines were created using WindPRO 3.4.388 software and associated Shadow module. The model is based on a "worst case" scenario where the model assumes that there are no clouds, the wind conditions allow for continuous turbine operation outside curtailment windows, the turbine is always directly between the receptor and the sun, and the turbine is always perpendicular to the sun. These calculations do not take into account the actual location and orientation of windows, or the screening effects associated with existing, site-specific conditions and obstacles such as trees and/or buildings.
