1.0 PROJECT OVERVIEW

Big Bend Wind, LLC (Big Bend or Applicant), an indirect subsidiary of Apex Clean Energy Holdings, LLC (Apex), is proposing to construct a wind energy generation facility, including up to 51 turbines and associated necessary project infrastructure, in Cottonwood County and Watonwan County, Minnesota (hereafter referred to as the Project) (see Figure 1). This report provides an assessment of the potential shadow flicker that could be experienced at residences located around the proposed turbines.

Two wind turbine models are being considered for the Project (see Table 1). Therefore, this analysis evaluated the potential shadow flicker for each turbine model. Each wind turbine consists of three major mechanical components: the tower, nacelle, and rotor. The dimensions for both wind turbine models under consideration for the Project are provided in Table 1. The Project's turbine layout is depicted in Figure 2.

Table 1. Big Bend Wind Turbine Model Characteristics

Turbine Model	Hub Height	Rotor Diameter	Total Height
Vestas V162	119 meters (390 feet)	162 meters (531 feet)	200 meters (656 feet)
GE 158	117 meters (384 feet)	158 meters (518 feet)	196 meters (643 feet)

The Project is located within Cottonwood and Watonwan Counties, Minnesota, approximately 7 miles northeast of the City of Windom and 30 miles north of the Minnesota-Iowa border. Elevations in the area range from approximately 1,100 feet above mean sea level (amsl) to 1,460 feet amsl. Land cover within the Project area is dominated by active agriculture, with farms and single-family residences generally occurring along the road frontage.

2.0 PROJECT UPDATES

EDR completed Shadow Flicker Reports in September 2021 (2021 Reports) that was included in the Big Bend Site Permit Amendment filing with the Minnesota Public Utilities Commission (MPUC). The MPUC approved the Project in September 2022. The 2021 Reports evaluated 53 turbine locations and three turbine models. EDR is providing this updated and simplified shadow flicker report (2025 Report) that reflects 51 turbine locations and two turbine models. Since the 2021 Reports, the Project has dropped two (2) turbine locations from consideration and there have been changes in receptors.

3.0 INTRODUCTION

Shadow flicker refers to the moving shadows that an operating wind turbine casts at times of the day when the turbine rotor is between the sun and a structure's position. Shadow flicker is most pronounced in northern latitudes during winter months because of the lower angle of the sun in the winter sky. However, it is possible to encounter shadow flicker anywhere for brief periods after sunrise and before sunset (U.S. Department of the Interior, 2005). During intervals of sunshine, wind turbine generators will cast a shadow on surrounding areas as the rotor blades pass in front of the sun, and if these moving shadows pass over a

window they can cause a flickering effect. Shadow flicker does not occur when fog or clouds obscure the sun, or when turbines are not operating.

The distance between a wind turbine and a structure affects the intensity of the shadows cast by the blades, and therefore the intensity of flickering. Shadows cast close to a turbine will be more intense, distinct, and focused. This is because a greater proportion of the sun's disc is intermittently blocked by the turbine (BERR, 2009). Obstacles such as terrain, vegetation, and/or buildings occurring between structures and wind turbines may significantly reduce or eliminate shadow-flicker effects. At distances beyond roughly 10 rotor diameters shadow-flicker effects are generally considered negligible (BERR, 2009; DECC, 2011; DOER, 2011).

The location and duration of shadow flicker can be predicted using computer modeling programs and input data regarding turbine characteristics and weather conditions. An "expected case" shadow flicker scenario is presented in this report based on a combination of real case data and conservative assumptions. The expected case aspects include sunshine frequency weather data (inclusion of percentage of monthly sunshine) and turbine rotor position (on-site wind direction data), while conservatively assumes that wind conditions allow continuous turbine operation. In addition, sunlight intensity and duration vary daily and seasonally, and obstacles that block shadows (terrain, vegetation, and buildings) exist in the landscape; these factors are not considered in the modeling, adding additional conservative measures.

4.0 METHODS

4.1 Shadow Flicker Analysis

This shadow flicker analysis evaluated the potential impact of 51 wind turbines for the two different turbine models listed in Table 1. A maximum distance of potential effect of 10 rotor diameters based on the wind turbine model (1,620 meters for the Vestas V162 and 1,580 meters for the GE 158) was used for these analyses to ensure that all potentially impacted residences were assessed.

The shadow flicker analysis for the proposed Project used *WindPRO 4.1* software and associated Shadow module. *WindPRO* is a widely accepted modeling software package developed specifically for the design and evaluation of wind power projects. Input variables and assumptions used for shadow flicker modeling calculations for the proposed Project include:

- The latitude and longitude coordinates of 51 proposed wind turbine sites (provided by the Applicant).
- The latitude and longitude coordinates of 973 potential residences located in the vicinity of the proposed turbines (provided by the Applicant).
- USGS DEM Elevation Data.
- The rotor diameter and hub height for both turbine models under consideration.
- Annual wind rose data (provided by Apex), which is depicted in Table A1 of Attachment A (to determine the approximate directional frequency of rotor orientation throughout the year).
- To account for the occurrence of cloudy conditions, the average monthly percent of available sunshine for the nearest National Oceanic and Atmospheric Administration (NOAA) weather station

in Minneapolis – St. Paul, Minnesota was used. Data were obtained from NOAA’s “Comparative Climatic Data for the United States through 2015” (see Table A2 of Attachment A) (<http://www.ncdc.noaa.gov>).

- No allowance was made for wind being below or above generation speeds. Blades are assumed to be moving during all daylight hours when the sun’s elevation is more than 3 degrees above the horizon. Shadow flicker is generally considered imperceptible when the sun is less than 3 degrees above the horizon (due to the scattering effect of the atmosphere on low angle sunlight) (States Committee for Pollution Control, 2002).

The model calculations include the cumulative sum of shadow flicker hours for all Project turbines. This omni-directional approach reports total shadow flicker results at a receptor regardless of the presence or orientation of windows at that particular residence (i.e., it assumes shadows from all directions can be perceived at a residence, which may or may not be true). A receptor in this “greenhouse” model is defined as a one square meter area located one meter above ground; actual house dimensions are not taken into consideration.

Because the shadow flicker analysis conducted for the proposed Project was based on the conservative assumptions that 1) the turbines are in continuous operation during daylight hours, and 2) that shadow flicker can be perceived at a receptor structure regardless of the presence or orientation of windows or the screening effects of all surrounding trees and buildings, the analysis presented herein is a conservative projection of the shadow-flicker effects.

4.2 Shadow Flicker Threshold

No consistent national, state, county, or local standards exist for allowable frequency or duration of shadow flicker from wind turbines. The Minnesota Public Utilities Commission has not promulgated any standards on shadow flicker. A threshold of 30 shadow flicker hours per year was applied to the analysis of the proposed Project to identify any potentially significant impacts on non-participating receptors.

5.0 RESULTS

Output from the model includes the following information:

- Calculated shadow-flicker time (total hours per year when shadow flicker is expected) at each of the 973 residences.
- Shadow isolines, which are used to create maps showing turbine locations, receptors, and projected shadow-flicker duration (hours per year) without taking into consideration the effect of screening provided by vegetation and structures (see Figures 3 and 4).

These data are presented in the tables included in Attachment B.

A summary of the projected shadow flicker at each of the receptors is presented in Table 2 below

Table 2. Summary of Expected Shadow Flicker

Hours/Year	Number of Receptors		
	Non-Participating Residence	Participating Residence	Total
<i>V162 with 119-meter hub height</i>			
0	800	58	858
0 – 1	5	0	5
1 – 10	37	11	48
10 – 20	9	13	22
20 – 30	3	18	21
Over 30	0	19	19
Max Hours/Year	25:36	59:00	--
<i>GE158 with 117-meter hub height</i>			
0	807	59	866
0 – 1	6	0	6
1 – 10	29	11	40
10 – 20	10	16	26
20 – 30	2	17	19
Over 30	0	16	16
Max Hours/Year	24:04	57:02	--

As these results indicate, all non-participating residences are modeled to receive less than 30 hours of shadow flicker per year for both turbine models (V162 and GE158). At most receptor locations, shadow flicker will occur primarily in the early morning or late afternoon.

Attachment B provides the results of the predicted shadow flicker at each receptor. The times of day and duration of shadow flicker experienced by each structure will vary throughout the calendar year based on the position of the sun in the sky and the direction of prevailing winds.

6.0 DISCUSSION

As outlined above, results of the shadow flicker analysis for the Project indicate that no non-participating residences are modeled to receive over 30 hours of shadow flicker per year.

In addition, the shadow flicker calculations presented herein do not take into account the actual location and orientation of windows, or the screening effects associated with existing, site-specific conditions and obstacles such as trees (i.e., does not take into account the results of a viewshed analysis) and/or buildings. Further, this analysis assumes turbine rotors are continuously in motion and that each receptor location is occupied year-round.

Given these assumptions, the predicted shadow-flicker frequency represents a conservative scenario, and almost certainly overstates the actual frequency of shadow flicker that would be experienced at any given

receptor location. In addition, many of the modeled shadow flicker hours are expected to be low intensity because they would occur during the early morning or late afternoon hours when the sun is low in the sky. As the sun sinks too low on the horizon and the distance to the sun becomes too long, the shadow dissipates before it reaches the ground (or the receptor) (EMD, 2021).

7.0 CONCLUSIONS

WindPRO predicted that 19 receptors will receive more than 30 hours/year of shadow flicker under the Vestas V162 scenario and 16 receptors will receive more than 30 hours/year of shadow flicker under the GE158 scenario from the Project. However, all of the receptors modeled to receive more than 30 hours/year are located on properties owned by Project participants. More generally, the assumptions underlying the shadow flicker analysis are conservative. The analysis does not take into account important real-world factors, including the actual location and orientation of windows and the screening effects associated with existing, site-specific conditions and obstacles such as trees and/or buildings. Also, the analysis assumes turbine rotors are in continuous motion. Given these assumptions, the predicted shadow-flicker frequency represents a conservative scenario and likely overstates the actual frequency of shadow flicker that would be experienced at any given receptor location.
